

FaithGuide: Architecture Note

A multimodal, denomination-aware Christian AI assistant architecture overview

Overview

FaithGuide is a multimodal, denomination-aware Christian AI assistant designed to prioritize strict scripture grounding, safety, and theological alignment. The architecture intentionally favors a lightweight frontend-first design using React directly connected to AI inference APIs, reducing operational complexity while maintaining strong safeguards against hallucination, misuse, and doctrinal inconsistencies.

Tech Stack

Component	Technology
Frontend	React 18 (Vite)
Text Generation API	OpenRouter (Mistral 7B / Auto Routing)
Image Generation API	Pollinations.ai (Flux Model, Free Tier)

Safety & Grounding Architecture (4-Layer Approach)

1. Client-Side Intercept

A regex-based pre-filter scans user prompts for adversarial or manipulative patterns such as attempts to rewrite scripture or justify harmful narratives. Blocked prompts bypass the API completely and return a hardcoded pastoral refusal response.

2. Dynamic Context Injection

The selected denomination (e.g., Catholic, Baptist, Orthodox) is dynamically injected into the system prompt before every inference request, ensuring theological alignment and denomination-aware responses.

3. Prompt-Level Guardrails

The system prompt enforces scripture citation formatting (Book Chapter:Verse), prevents hallucinated verses, gently corrects fake scripture references, and requires hedging for uncertain

historical claims.

4. Multimodal Filtering

Image prompts are scanned for occult, violent, or inappropriate keywords before being appended with reverent visual modifiers such as sacred, divine lighting, and routed securely to the Pollinations Flux image generation API.

Conversation Memory

Stateful memory is managed using an in-session React state array. The entire conversation history is serialized and passed to the OpenRouter API during every request, enabling contextual follow-up conversations without requiring a dedicated database during the MVP phase.

Future Production Roadmap

For production-scale deployment, the architecture can evolve into a more robust distributed system that includes:

- A dedicated Node.js / Express backend for secure API orchestration
- A vector database such as Pinecone or Weaviate for Retrieval-Augmented Generation (RAG) across biblical texts
- Persistent session storage using PostgreSQL
- Authentication, rate limiting, and analytics infrastructure
- Advanced moderation pipelines and caching layers for scalability

Prepared as a concise architecture summary for FaithGuide AI.
